

# A simple two-dimensional parameterisation for Flux Footprint Prediction (FFP)

For details of the derivation of the footprint parameterisation, see

Kljun, N., P. Calanca, M.W. Rotach, H.P. Schmid, 2015: A simple two-dimensional parameterisation for Flux Footprint Prediction (FFP). *Geosci. Model Dev.*, 8, 3695-3713. doi:10.5194/gmd-8-3695-2015.

Please acknowledge the source of your footprint estimates by citing the above article. Thanks!

## How to use FFP R code

The FFP function is not meant to be a stand-alone function, but a function that can be called from within your own data processing code. For example, FFP can be called from within a loop of your own R function to calculate a series of footprints for a selected time series of your flux data.

### 1) Single footprint

To calculate a single FFP flux footprint, call **calc\_footprint\_FFP** as described below. To rotate a single flux footprint into the main wind direction, call **calc\_footprint\_FFP** with an optional input value for the wind direction. To derive the source area of R% of the flux footprint, call **calc\_footprint\_FFP** with an optional additional single value of R (e.g., 80 or 0.8 for 80%), or with an array of Rs (e.g., c(20, 40, 60, 80) or seq(10, 80, 10)).

```
FFP <- calc_footprint_FFP(zm,z0,umean,h,ol,sigmav,ustar)
```

### FFP Input

All inputs as scalars

zm = Measurement height above displacement height (i.e. z-d) [m]  
z0 = Roughness length [m] - enter [NaN] if not known  
umean = Mean wind speed at zm [ms<sup>-1</sup>] - enter [NaN] if not known  
h = Boundary layer height [m]  
ol = Obukhov length [m]  
sigmav = standard deviation of lateral velocity fluctuations [ms<sup>-1</sup>]  
ustar = friction velocity [ms<sup>-1</sup>]

Note: Either z0 or umean is required. If both are given, z0 is selected to calculate the footprint.

*Optional input:*

wind\_dir = Wind direction in degrees (of 360) for rotation of the footprint  
r = Percentage of source area, i.e. a value between 10% and 90%.  
Can be either a single value (e.g., "80") or an array of increasing percentage values (e.g., " seq(10, 80, 10)")  
Expressed either in percentages ("80") or in fractions of 1 ("0.8")  
Default is [10:10:80]. Set to "NaN" for no output of percentages  
nx = Integer scalar defining the number of grid elements of the scaled footprint. Large nx results in higher spatial resolution and higher computing time. Default is 1000, nx must be >=600.  
rslayer = Calculate footprint even if zm within roughness sublayer: set rslayer = 1. Note that this only gives a rough estimate of the footprint as the model is not valid within the roughness sublayer. Default is 0 (i.e. no footprint for within RS). z0 is needed for estimation of the RS.  
crop = Crop output area to size of the 80% footprint or the largest r given if crop=1

## FFP output

FFP = Structure array with footprint data with footprint data for measurement at [0 0 zm] m  
x\_ci\_max = x location of footprint peak (distance from measurement) [m]  
x\_ci = x array of crosswind integrated footprint [m]  
f\_ci = Footprint function values of crosswind integrated footprint [m<sup>-1</sup>]  
x\_2d = x-grid of 2-dimensional footprint [m], rotated if wind\_dir is provided  
y\_2d = y-grid of 2-dimensional footprint [m], rotated if wind\_dir is provided  
f\_2d = footprint function values of 2-dimensional footprint [m<sup>-2</sup>]  
r = percentage of footprint as in input, if provided  
fr = footprint value at r, if r is provided  
xr = x-array for contour line of r, if r is provided  
yr = y-array for contour line of r, if r is provided  
flag\_err = 1 in case of error, 0 otherwise

## Example

```
FFP <- calc_footprint_FFP(zm=20,z0=0.01,h=2000,ol=-100,sigmav=0.6,ustar=0.4, wind_dir=30,  
r=seq(10,80,10))
```

## 2) Single footprint within a given, fixed domain

In some cases it may be useful to derive a footprint for a pre-set given domain. For such a case, use **calc\_footprint\_FFP\_climatology** with a single set of input parameters. For details of input and output parameters, see Section 3 below.

## 3) Footprint climatology

A footprint climatology is an aggregation of footprints over several time steps. To calculate a footprint climatology with FFP, call **calc\_footprint\_FFP\_climatology** as described below. Again, optional input parameters can be provided to, for example, derive the source area of R% of the flux footprint climatology, call **calc\_footprint\_FFP\_climatology** with an optional additional single value of R (e.g., 80 for 80%), or with an array of Rs (e.g., c(20, 40, 60, 80) or seq(10, 80, 10)). You can also plot an example figure of your footprint climatology by setting fig = 1.

This function calculates footprints within a fixed physical domain (either default area or user input). For determining the optimal extent of the domain (large enough to include the footprints) use the function **calc\_footprint\_FFP** as described in Section 1.

Important: to run **calc\_footprint\_FFP\_climatology**, the "spatialfil" and "EBImages" packages need to be installed. See Section 5 for information on how to install EBImages.

## FFP Input

All vectors need to be of equal length (one value for each time step, scalars possible)

zm = Measurement height above displacement height (i.e. z-d) [m]

Usually a scalar, but can also be a vector

z0 = Roughness length [m] - enter [NaN] if not known

Usually a scalar, but can also be a vector

umean = Mean wind speed at zm [ms<sup>-1</sup>] - enter [NaN] if not known

Either z0 or umean is required. If both are given, z0 is selected to calculate the footprint

h = Vector of boundary layer height [m]

`ol` = Vector of Obukhov length [m]  
`sigmav` = Vector of standard deviation of lateral velocity fluctuations [ $\text{ms}^{-1}$ ]  
`ustar` = Vector of friction velocity [ $\text{ms}^{-1}$ ]  
`wind_dir` = Vector of wind direction in degrees (of 360) for rotation of the footprint

*Optional input:*

`domain` = Domain size as an array of (xmin xmax ymin ymax) [m].  
 Footprint will be calculated for a measurement at [0 0 zm] m  
 Default is smallest area including the r% footprint or (-1000, 1000, -1000, 1000) m, whichever smallest (80% footprint if r not given).  
`dx, dy` = Cell size of domain [m]  
 Small dx,dy result in higher spatial resolution and higher computing time  
 Default is dx = dy = 2 m (if neither domain nor nx and ny are given).  
 If only dx is given, dx=dy.  
`nx, ny` = Two integer scalars defining the number of grid elements in x and y  
 Large nx and ny result in higher spatial resolution and higher computing time  
 Default is nx = ny = 1000. If only nx is given, nx=ny  
 If dx,dy and nx,ny are given, dx,dy is given priority  
`r` = Percentage of source area, i.e. a value between 10% and 90%.  
 Can be either a single value (e.g., "80") or an array of increasing percentage values (e.g., "seq(10, 80, 10)")  
 Expressed either in percentages ("80") or in fractions of 1 ("0.8")  
 Default is [10:10:80]. Set to "NaN" for no output of percentages  
`rslayer` = Calculate footprint even if zm within roughness sublayer: set rslayer = 1. Note that this only gives a rough estimate of the footprint as the model is not valid within the roughness sublayer. Default is 0 (i.e. no footprint for within RS). z0 is needed for estimation of the RS.  
`smooth_data` = Apply convolution filter to smooth footprint climatology if smooth\_data=1 (default)  
`crop` = Crop output area to size of the 80% footprint or the largest r given if crop=1  
`pulse` = Display progress of footprint calculations every pulse-th footprint (e.g., "100")  
`fig` = Plot an example figure of the resulting footprint (on the screen): set fig = 1.  
 Default is 0 (i.e. no figure)

**FFP output**

`FFP` = Structure array with footprint data with footprint data for measurement at [0 0 zm] m  
`x_2d` = x-grid of footprint climatology [m]  
`y_2d` = y-grid of footprint climatology [m]  
`fclim_2d` = Normalised footprint function values of footprint climatology [ $\text{m}^{-2}$ ]  
`r` = Percentage of footprint as in input, if provided  
`fr` = footprint value at r, if r is provided  
`xr` = x-array for contour line of r, if r is provided  
`yr` = y-array for contour line of r, if r is provided  
`n` = Number of footprints calculated and included in footprint climatology  
`flag_err` = 1 in case of error, 2 if not all contour plots (r%) within specified domain, 0 otherwise  
 If the source area is calculated for 20%, 40%, 60% and 80%, and the 80% contour is extending further than the domain (but the other r's are within the domain), flag\_err = 2 and all results are provided apart from those for the contour at 80%.

**Example**

```

FFP <- calc_footprint_FFP_climatology(zm=20, z0=0.01, umean=NA, h=c(2000,1800,1500),
  ol=c(-10,-100,-500), sigmav=c(0.9,0.7,0.3), ustar=c(0.5,0.3,0.4), wind_dir=c(30,50,70),
  domain=c(-100,1000,-100,1000), nx=1100, r=seq(10,80,10), smooth_data=1)
  
```

#### 4) Plotting footprints

To plot the footprint climatology, you can set `fig=1` when calling it. Or, in R, type, for example

Crosswind-integrated footprint

```
plot(FFP$x_ci,FFP$f_ci, type="l")
```

Two-dimensional view of single footprint (from `calc_footprint_FFP.R`) with contour lines of R% (using the `fields` package). Note that `nx` and `ny` of `quilt.plot` need to be adjusted for your output.

```
ffp_x <- c(FFP$x_2d)
ffp_y <- c(FFP$y_2d)
ffp_f <- c(FFP$f_2d)
quilt.plot(ffp_x,ffp_y,ffp_f,nx=1000,ny=1000, xlim=c(-100,1000),ylim=c(-100,1000))
for (i in 1:8) lines(FFP$xr[[i]],FFP$yr[[i]], type="l", col="red")
```

Two-dimensional view of footprint climatology with contour lines of R%.

```
image.plot(FFP$x_2d[1,], FFP$y_2d[,1], FFP$fclim_2d)
for (i in 1:8) lines(FFP$xr[[i]], FFP$yr[[i]], type="l", col="red")
```

Three-dimensional footprint climatology surface (using the `plot3D` package)

```
surf3D(FFP$x_2d, FFP$y_2d,FFP$fclim_2d)
```

Please note that the plotting convention for matrices varies with software package or even with the selected plotting command, i.e. point (1/1) of the matrix may be the lower left corner or the upper left corner. It hence is suggested that **the footprint plot is always checked against a wind rose**. For complex footprint climatologies, it is sufficient to check just one single footprint. It may be necessary to transpose the footprint matrix depending on the plotting tool.

#### 5) Required R packages

The footprint code requires the following R packages / libraries: `jpeg`, `fields`, `zoom`, `EBImage`.

Please refer to R-specific help pages for instructions on how to install these.

For help with `EBImage`, see <https://www.bioconductor.org/packages/release/bioc/html/EBImage.html>
